Variable declaration

Type of a variable

Every variable in C has a type.

- The type is **fully deterministic** and **cannot be changed**.
- The type is **known even when the program is not run**.
 - \rightarrow The type is known at **compile-time**.
 - \rightarrow C is **statically-typed** \wedge $\textcolor{red}{\{1\}}$. \rightarrow C has a **static type system**.
 - In contrast, Python is **dynamically-typed**.

Statically-typed vs dynamically-typed

Python: dynamically typed

```
a = 42          # Type of a is int.  
a = "hello"     # Type of a becomes str.
```

The type of a variable

- can be changed, and
- is not necessarily known until we run the program.

C: statically-typed

```
int a = 42; // Type of a is int.  
a = "hello"; // Error! Types mismatch!
```

The type of a variable

- is explicitly written on declaration, and
- is known at compile-time, and
- cannot be changed.

A type-related error in C is (*usually*) a **compile error**:

- It stops the compiler. The executable will not be generated.

Declare a variable

To declare a variable, we need to specify its **type** and **name**.

```
Type name;
```

Example:

```
int x; // Declares a variable named `x`, whose type is  
`int`.  
double y; // Declares a variable named `y`, whose type is  
`double`.
```

We may declare multiple variables of a same type in one declaration statement, separated by `,`:

```
int x, y; // Declares two variables `x` and `y`, both having  
type `int`.
```

Declare a variable

A **variable declaration** can be placed

- inside a function, which declares a **local variable**, or
- outside of any functions, which declares a **global variable**.

```
#include <stdio.h>

int x, y; // global variables

int main(void) {
    scanf("%d%d", &x, &y);
    printf("%d\n", x + y);
}
```

```
#include <stdio.h>

int main(void) {
    // local variables in `main`
    int x, y;
    scanf("%d%d", &x, &y);
    printf("%d\n", x + y);
}
```

Local variables vs global variables

Which one do you prefer?

```
#include <stdio.h>

int x, y; // global variables

int main(void) {
    scanf("%d%d", &x, &y);
    printf("%d\n", x + y);
}
```

```
#include <stdio.h>

int main(void) {
    // local variables in `main`
    int x, y;
    scanf("%d%d", &x, &y);
    printf("%d\n", x + y);
}
```

What are these variables used for?

```
#include <stdio.h>
// Other #includes

int x, y; // what are these two variables used for?

int moveSpaceShuttle(SpaceShuttle *shuttle, Coord to, Vehicle
*by) {
    // 109 lines
}

int makePreparations(Environment *env, Task tasks[], Time time)
{
    // 73 lines
}
```

```
}  
LaunchResult launchSpaceshuttle(SpaceShuttle *shuttle, Task  
tasks[]) {  
    // 35 lines  
}  
// other 136 functions, 3325 lines in total  
int main(void) {  
    // 120 lines  
}
```

Readability matters

[Best practice] Declare the variable when you first use it!

- If the declaration and use of the variable are too separated, it will become much more difficult to figure out what they are used for as the program goes longer.

[Best practice] Use meaningful names!

- The program would be a mess if polluted with names like `a`, `b`, `c`, `d`, `x`, `y`, `cnt`, `cnt_2`, `flag1`, `flag2`, `flag3` everywhere.
- Use meaningful names: `sumOfScore`, `student_cnt`, `open_success`, ...

Readability is very important. Many students debug day and night simply because their programs are not human-readable.

Use of global variables

One reason for using global variables is to have them shared between functions:

```
int input;
void work(void) {
    printf("%d\n", input);
}
int main(void) {
    scanf("%d", &input);
    work();
}
```

```
void work(void) {
    // Error: `input` was not decared
    // in this scope.
    printf("%d\n", input);
}
int main(void) {
    int input;
    scanf("%d", &input);
    work();
}
```

\$\rightarrow\$ More about scopes and name lookup in later lectures / recitations.

Initialize a variable

A variable can be **initialized** on declaration.

```
int x = 42; // Declares the variable `x` of type `int`,  
           // and initializes its value to 42.  
int a = 0, b, c = 42; // Declares three `int` variables, with  
`a` initialized  
                      // to 0, `c` initialized to 42, and `b`  
uninitialized.
```

This is syntactically **different** (though seems equivalent) to

```
int x; // Declares `x`, uninitialized.  
x = 42; // Assigns 42 to `x`.
```

[Best practice] Initialize the variable if possible. Prefer initialization to later assignment.

\$\rightarrow\$ More on initialization in later lectures.

Arithmetic types

Refer to [this page](#) for a complete, detailed and standard documentation.

Integer types

Is `int` equivalent to \mathbb{Z} ?

- Is there a limitation on the numbers that `int` can represent?
-

Integer types

Is `int` equivalent to \mathbb{Z} ?

- Is there a limitation on the numbers that `int` can represent?

Experiment:

```
#include <stdio.h>

int main(void) {
    int x = 1;
    while (1) {
        printf("%d\n", x);
        x *= 2; // x = x * 2
        getchar();
    }
}
```

- On 64-bit Ubuntu 22.04 and compiled with GCC 13, after printing `1073741824` (2^{30}), the output becomes negative, and then `0`.

```
1073741824
-2147483648
0
0
```

Bits and bytes

Information is stored in computers **in binary**.

- $42_{\text{ten}} = 101010_{\text{two}}$.

A **bit** is either 0 or 1.

- The binary representation of 42 consists of 6 bits.

A **byte** is 8 bits 2^2 grouped together like 10001001.

- At least 1 byte is needed to store 42.
- At least 3 bytes are needed to store $142857_{\text{ten}} = 100010111000001001_{\text{two}}$

Bits and bytes

A 32-bit number:

$2979269462_{\text{ten}} = 10110001100101000000101101010110_{\text{two}}$.

Suppose now we have n bits.

- How many different values can be represented?
 - What is the largest integer that can be represented?
 - How do we represent negative numbers? Non-integer values? ...
-

Bits and bytes

Suppose now we have n bits.

- How many different values can be represented?
 - 2^n .
 - What is the largest integer that can be represented?
 - $2^{n-1} = \underbrace{111\dots 1}_n$ in **two's complement**.
 - How do we represent negative numbers? Non-integer values? ...
 - There are several different [signed number representations](#), among which **two's complement** is widely used.
 - About floating-point numbers: [IEEE754](#)
 - Details are not covered in CS100.
-

Integer types

An integer type in C is either **signed** or **unsigned**, and has a **width** denoting the number of bits that can be used to represent values.

Suppose we have an integer type of n bits in width.

- If the type is **signed**, the range of values that can be represented is $[-2^{n-1}, 2^{n-1}-1]$.
 - If the type is **unsigned**, the range of values that can be represented is $[0, 2^n-1]$.
-

Integer types

(signed)
short (int)

unsigned
short (int)

signed / int /
signed int

unsigned (int)

(signed) long (int)

unsigned long (int)

(signed) long long (int)

unsigned long long (int)

Integer types

- The keyword `int` is optional in types other than `int`:
 - e.g. `short int` and `short` name the same type.
 - e.g. `unsigned int` and `unsigned` name the same type.
- "Unsigned-ness" needs to be written explicitly: `unsigned int`, `unsigned long`, ...
- Types without the keyword `unsigned` are signed by default:
 - e.g. `signed int` and `int` name the same type.
 - e.g. `signed long int`, `signed long`, `long int` and `long` name the same type.

Width of integer types

type	width (at least)	width (usually)
<code>short</code>	16 bits	16 bits
<code>int</code>	16 bits	32 bits
<code>long</code>	32 bits	32 or 64 bits
<code>long long</code>	64 bits	64 bits

- A signed type has the same width as its `unsigned` counterpart.
- **It is also guaranteed that** `sizeof(short) \leq sizeof(int) \leq sizeof(long) \leq sizeof(long long)`.
 - `sizeof(T)` is the number of **bytes** that `T` holds.

Implementation-defined behaviors

The standard states that the exact width of the integer types is **implementation-defined**.

- **Implementation:** The compiler and the standard library.
- An implementation-defined behavior depends on the compiler and the standard library, and is often also related to the hosted environment (e.g. the operating system).

Which one should I use?

`int` is the most optimal integer type for the platform.

- Use `int` for integer arithmetic by default.
- Use `long long` if the range of `int` is not large enough.
- Use smaller types (`short`, or even `unsigned char`) for memory-saving or other special purposes.

- Use `unsigned` types for special purposes. We will see some in later lectures.
-

Which one is the real world, the integer types or \mathbb{Z} ?

Real floating types

"Floating-point": The number's radix point can "float" anywhere to the left, right, or between the significant digits of the number.

Real floating-point types can be used to represent *some* real values.

- Real floating-point types $\neq \mathbb{R}$.
-

Real floating types

C has three types for representing real floating-point values:

- `float`: single precision. Matches [IEEE754 binary32 format](#) if supported.
- `double`: double precision. Matches [IEEE754 binary64 format](#) if supported.
- `long double`: extended precision. A floating-point type whose precision and range are at least as good as those of `double`.

Details of IEEE754 formats are not required in CS100.

Range of values can be found in [this table](#).

Which one should I use?

Use `double` for real floating-point arithmetic by default.

- In some cases the precision of `float` is not enough.
- Don't worry about efficiency! `double` arithmetic is not necessarily slower than `float`.

Do not use floating-point types for integer arithmetic!

scanf/printf

Refer to the table in [this page](#).

type	format specifier
<code>short</code>	<code>%hd</code>
<code>int</code>	<code>%d</code>
<code>long</code>	<code>%ld</code>
<code>long long</code>	<code>%lld</code>

type	format specifier
<code>unsigned short</code>	<code>%hu</code>
<code>unsigned</code>	<code>%u</code>
<code>unsigned long</code>	<code>%lu</code>
<code>unsigned long long</code>	<code>%llu</code>

- `%f` for `float`, `%lf` for `double`, and `%Lf` for `long double`.

Exercise

Write the "A+B" program for real numbers. Which type do you decide to use? How do you read and print the values?

Exercise

Write the "A+B" program for real numbers. Which type do you decide to use? How do you read and print the values?

```
#include <stdio.h>

int main(void) {
    double a, b;
    scanf("%lf%lf", &a, &b);
    printf("%lf\n", a + b);
    return 0;
}
```

Character types

The C standard provides three **different** character types: `signed char`, `unsigned char` and `char`.

Let `T` $\in \{\text{signed char}, \text{unsigned char}, \text{char}\}$. It is guaranteed that

`1 == sizeof(T) <= sizeof(short) <= sizeof(int) <= sizeof(long) <= sizeof(long long)`.

- `T` takes exactly 1 byte.

Question: What is the valid range of `signed char`? `unsigned char`?

Character types

Question: What is the valid range of `signed char`? `unsigned char`?

- `signed char`: $[-128, 127]$.
- `unsigned char`: $[0, 255]$.

What? A character is an integer?

ASCII (American Standard Code for Information Interchange)

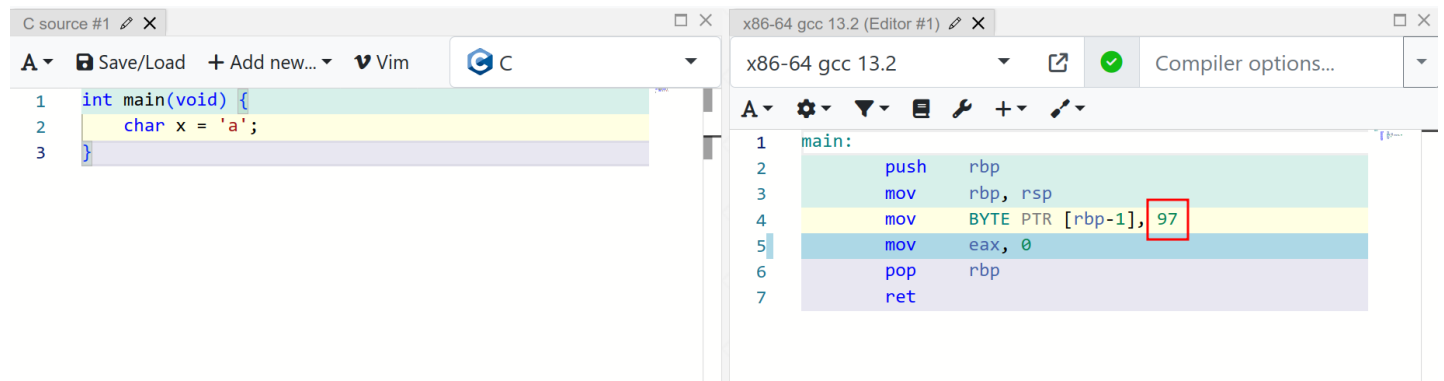

A character is represented in computers as its [ASCII code](#), which is a small integer.

Decimal	Hex	Char	Decimal	Hex	Char	Decimal	Hex	Char	Decimal	Hex	Char

ASCII (American Standard Code for Information Interchange)

A character is represented in computers as its [ASCII code](#), which is a small integer.

- We only consider the so-called *ASCII characters* here.

A character is **nothing but** an integer! In C, there is no "conversion" between characters and ASCII code!

ASCII (American Standard Code for Information Interchange)

Important things to remember:

- $[\$ '0' \$, \$ '9' \$] = [48, 57] \$$.
- $[\$ 'A' \$, \$ 'Z' \$] = [65, 90] \$$.
- $[\$ 'a' \$, \$ 'z' \$] = [97, 122] \$$.

Example: Given a lowercase letter, return its uppercase form.

```
char to_uppercase(char x) {  
    return x - 32;  
}
```

[Best practice] Avoid magic numbers

What is the meaning of 32 here? \rightarrow a magic number.

```
char to_uppercase(char x) {  
    return x - 32;  
}
```

Write it in a more human-readable way:

```
char to_uppercase(char x) {  
    return x - ('a' - 'A');  
}
```

Escape sequence

Some special characters are not directly representable: newline, tab, quote, ...

We use [escape sequences](#), e.g.

escape sequence	description
<code>\'</code>	single quote
<code>\"</code>	double quote
<code>\\</code>	backslash

escape sequence	description
<code>\n</code>	newline
<code>\r</code>	carriage return
<code>\t</code>	horizontal tab

Character types

`char`, `signed char` and `unsigned char` are **three different types**.

- Whether `char` is signed or unsigned is **implementation-defined**.
- If `char` is signed (unsigned), it represents the same set of values as the type `signed char` (`unsigned char`), but **they are not the same type**.
 - In contrast, `T` and `signed T` are the same type for `T` \in {`short`, `int`, `long`, `long long`}.

Character types

For almost all cases, use `char` (or, sometimes `int`) to represent characters.

`signed char` and `unsigned char` are used for other purposes.

To read/print a `char` using `scanf`/`printf`, use `%c`.

Sad story: Handling non-ASCII characters? ...

``

Sad story: Handling non-ASCII characters? ...

Even though the standard provides `wchar_t`, `char8_t` (since C23), `char16_t` and `char32_t` to handle wide/Unicode characters, there are still a lot of problems.

C++23 has some improvement.

That's why Python people laugh at us ...

Boolean type: `bool` (since C99)

A type that represents true/false, 0/1, yes/no, ...

To access the name `bool`, `true` and `false`, `<stdbool.h>` is needed. (until C23)

Example: Define a function that accepts a character and returns whether that character is a lowercase letter.

Before C99, using `int`, `0` and `1`:

```
int is_lowercase(char c) {  
    if (c >= 'a' && c <= 'z')  
        return 1;  
    else  
        return 0;  
}
```

Since C99, using `bool`, `false` and `true`:

```
bool is_lowercase(char c) {  
    if (c >= 'a' && c <= 'z')  
        return true;  
    else  
        return false;  
}
```

Boolean type: `bool` (since C99)

Before C99, using `int`, `0` and `1`:

```
int is_lowercase(char c) {  
    if (c >= 'a' && c <= 'z')  
        return 1;  
    else  
        return 0;  
}
```

Since C99, using `bool`, `false` and `true`:

```
bool is_lowercase(char c) {  
    if (c >= 'a' && c <= 'z')  
        return true;  
    else  
        return false;  
}
```

Both return values can be used as follows:

```
char c; scanf("%c", &c);  
if (is_lowercase(c)) {  
    // do something when c is lowercase ...  
}
```

[Best practice] Simplify your code

Just return the result of the condition expression.

```
int is_lowercase(char c) {  
    return c >= 'a' && c <= 'z';  
}
```

```
bool is_lowercase(char c) {  
    return c >= 'a' && c <= 'z';  
}
```

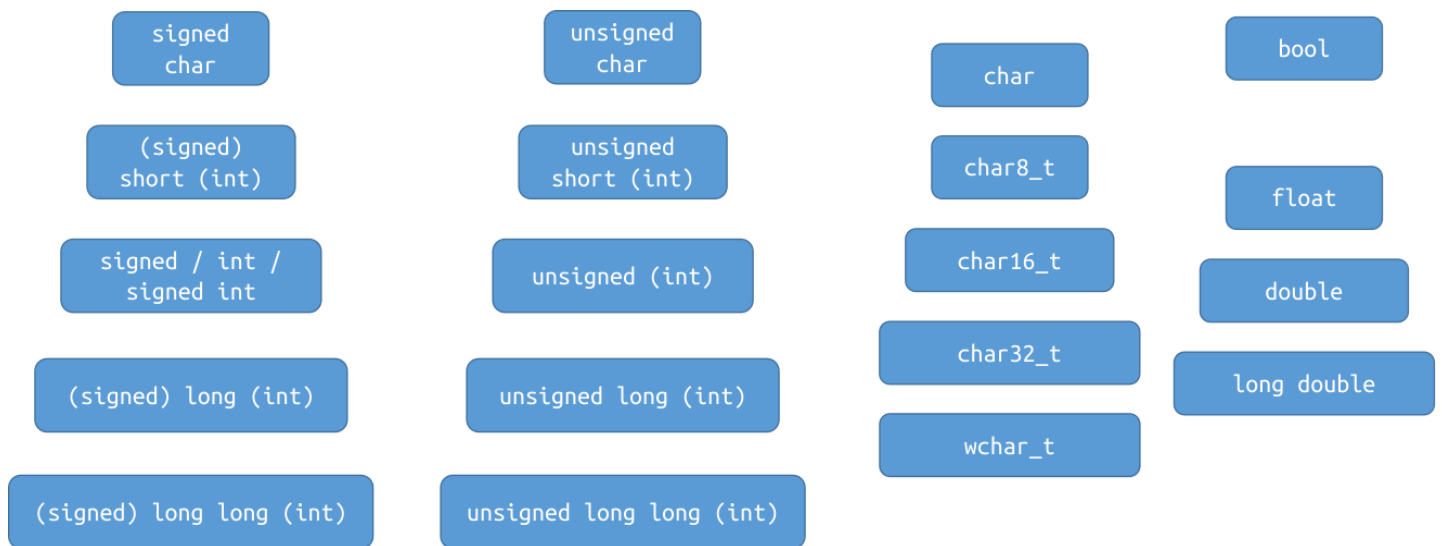

We will introduce the operators (&&, <=, >=) involved here in later lectures.

Summary

- Variable declaration
 - Type + name
 - Multiple variables in one declaration statement
 - Global vs local
 - Initialization
-

Summary

- Arithmetic types

Summary

- Arithmetic types
 - Width, signed-ness, valid range
 - Which type to choose
 - Characters: ASCII code, escape sequence
 - Boolean

Exercise

Write a simple calculator that handles input of the form `x op y`, where `x` and `y` are floating-point numbers and `op` `{ '+', '-', '*', '/' }`. You may use a group of `if-else` statements like this:

```
if (op == '+') {  
    // ...  
} else if (op == '-') {  
    // ...  
} else if (op == '*') {  
    // ...  
} else if (op == '/') {  
    // ...  
} else {  
    // report an error  
}
```

Notes

$\textcolor{red}{1}$ The type of every expression in C is determined at compile-time except for *variable-length arrays* (since C99).

$\textcolor{red}{2}$ A byte is 8 bits on most platforms, but we do have exceptions: [36-bit computing](#).

$\textcolor{red}{3}$ There are several different signed number representations, but all popular machines and almost all compilers use **two's complement**. Before C23 and C++20, the C/C++ standards allow for all possible representations, so the minimal valid range for a n -bit integer is $\left[-2^{n-1}+1, 2^{n-1}-1\right]$, which is the range for *one's complement* and *sign-and-magnitude*. Since C23 and C++20, the only representation allowed is two's complement, so the valid range is guaranteed to be $\left[-2^{n-1}, 2^{n-1}-1\right]$. In CS100 we still assume that two's complement is used, even though we are based on C17/C++17.
